Abstract

Browsers do not offer native elements that allow for rich-text editing. There are third-party libraries that emulate these elements by utilizing the `contenteditable`-attribute. However, the API enabled by `contenteditable` is limited and unstable. Bugs and unwanted behavior can only be worked around and not fixed. The library "Type" demonstrates that rich-text editing can be achieved without requiring the `contenteditable` attribute, thus solving many problems contemporary third-party rich-text editor libraries have.

Thesis Supervisor: Prof. Dr. Debora Weber-Wulff
Title: Associate Professor

Acknowledgments

I would like to extend my thanks to my supervisor Prof. Dr. Debora Weber-Wulff for giving me the opportunity to work on a topic I have been passionate about for years.

I would like to thank Marijn Haverbeke for his work on CodeMirror, from which I could learn a lot.

I would like to thank my father for supporting me. Always.

Chapter 1

Introduction

1.1 Motivation

Rich-text editors are commonly used by many on a daily basis. Often, this happens knowingly, for instance in an office suite, when users wilfully format text. But often, rich-text editors are being used without notice. For instance when writing e-mails, entering a URL inserts a link automatically in many popular e-mail-applications. Also, many applications, like note-taking apps, offer rich-text capabilities that go unnoticed. Many users do not know the difference between rich-text and plain-text writing. Rich-text editing has become a de-facto standard, that to many users is *just there*. Even many developers do not realise that formatting text is a feature that needs special implementation, much more complex than plain-text editing.

While there are APIs for creating rich-text input controls in many desktop programming environments, web-browsers do not offer native rich-text inputs. However, third-party JavaScript libraries fill the gap and enable developers to include rich-text editors in web-based projects.

The libraries available still have downsides. Most importantly, only a few of them work. As a web-developer, the best choices are either to use CKEditor or TinyMCE. Most other editors are prone to bugs and unwanted behaviour. Piotrek Koszuliński, core developer of CKEditor comments this on StackOverflow as follows:

*Don't write wysiwyg editor[sic] - use one that exists. It's going to consume all your time and still your editor will be buggy. We and guys from other... two main editors (guess why only three exist) are working on this for years and we still have full bugs lists ;).*¹

A lot of the bugs CKEditor and other editors are facing are due to the fact that they rely on so-called "HTML Editing APIs" that have been implemented in browsers for years, but only been standardized with HTML5. Still, to this present day, the implementations are prone to numerous bugs and behave inconsistently across different browsers. And even though these APIs are the de-facto standard for implementing rich-text editing, with their introduction in Internet Explorer 5.5, it has never been stated they have been created to be used as such.

It's a fact, that especially on older browsers, rich-text editors have to cope with bugs and inconsistencies, that can only be worked around, but not fixed, as they are native to the browser. On the upside, these APIs offer a high-level API to call so-called "commands" to format the current text-selection.

However, calling commands will only manipulate the document's DOM tree, in order to format the text. This can also be achieved without using editing APIs, effectively avoiding unfixable bugs and enabling a consistent behaviour across all browsers.

Furthermore CKEditor, TinyMCE and most other libraries are shipped as user interface components. While being customizable, they tend to be invasive to web-projects.

This thesis demonstrates a way to enable rich-text editing in the browser without requiring HTML Editing APIs, provided as a GUI-less software library. This enables web-developers to implement rich-text editors specific to the requirements of their web-projects.

1.2 Terminology

rich-text, WYSIWYG, word-processing, WYSIWYM

1.3 Structure

The first part of this thesis explains rich-text editing on desktop PCs. The second part explains how rich-text editors are currently being implemented in a browser-environment and the major technical differences to the desktop. Part three will cover the downsides and the problems that arise with the current techniques used. Part four will explain how rich-text editing can be implemented on the web bypassing these problems. Part five dives into the possibilities of web-based rich-text editing in particular when using the techniques explained in this thesis.

Chapter 2

Text editing in desktop environments

2.1 Basics of plain-text editing

caret selection input

2.2 Basics of rich-text editing

document tree formatting algorithms

2.3 Libraries for desktop environments

It is no longer needed to implement basic rich-text editing components from the ground up. Rich-text editing has become a standard and most modern Frameworks, system APIs or GUI libraries come with built-in capabilities. Table 2.1 lists rich-text text components for popular languages and frameworks.

Environment	Component
Java (Swing)	JTextPane / JEditorPane
MFC	CRichEditCtrl
Windows Forms / .NET	RichTextBox
Cocoa	NSTextView
Python	Tkinter Text
Qt	QTextDocument

Table 2.1: Rich-text components in desktop environments

Chapter 3

Text editing in browser environments

3.1 Plain-text inputs

Text input components for browsers have been introduced with the specification of HTML 2.0¹. The components proposed include inputs for single line (written as `<input type="text" />`) and multiline texts (written as `<textarea></textarea>`). These inputs allow writing plain-text only.

3.2 Rich-text editing

Major browsers, i.e. any browser with a market share above 0.5%², do not offer native input fields that allow rich-text editing. Neither the W3C's HTML5 and HTML5.1 specifications nor the WHATWG HTML specification recommend such elements. However, by being able to display HTML, browsers effectively are rich-text viewers. By the early 2000s, the first JavaScript libraries emerged, that allowed users to interactively change (parts of) the HTML of a website, to enable rich-text editing in the browser. The techniques used will be discussed in section 3.2.1 through section 3.2.4.

Attribute	Type	Can be set to	Possible values
designMode	IDL attribute	Document	"on", "off"
contentEditable	IDL attribute	Specific HTMLElements	boolean, "true", "false", "inherit"
contenteditable	content attribute	Specific HTMLElements	empty string, "true", "false"

Table 3.1: Editing API attributes

3.2.1 HTML Editing APIs

In July 2000, with the release of Internet Explorer 5.5, Microsoft introduced the IDL attributes `contentEditable` and `designMode` along with the content attribute `contenteditable`³⁴. These attributes were not part of the W3C’s HTML 4.01 specifications⁵ or the ISO/IEC 15445:2000⁶, the defining standards of that time. Table 3.1 lists these attributes and possible values.

```

1 <div contenteditable="true">
2   This text can be edited by the user.
3 </div>
```

Listing 3.1: An element set to editing mode

By setting `contenteditable` or `contentEditable` to "true" or `designMode` to "on", Internet Explorer 5.5 switches the affected elements and their children to an editing mode. The `designMode` can only be applied to the entire document and the `contentEditable` and `contenteditable` attributes can be applied to specific HTML elements as described on Microsoft’s Developer Network (MSDN) online documentation⁷. These elements include "divs", "paragraphs" and the document’s "body" element amongst others. In editing mode

1. Users can interactively click on and type inside texts
2. An API is enabled that can be accessed via JScript and JavaScript

³[https://msdn.microsoft.com/en-us/library/ms533720\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/ms533720(v=vs.85).aspx), last checked on 07/10/2015

⁴[https://msdn.microsoft.com/en-us/library/ms537837\(VS.85\).aspx](https://msdn.microsoft.com/en-us/library/ms537837(VS.85).aspx), last checked on 07/10/2015

⁵<http://www.w3.org/TR/html401/>, last checked on 07/14/2015

⁶http://www.iso.org/iso/iso_catalogue/catalogue_tc/catalogue_detail.htm?csnumber=27688, last checked on 07/14/2015

⁷[https://msdn.microsoft.com/en-us/library/ms537837\(VS.85\).aspx](https://msdn.microsoft.com/en-us/library/ms537837(VS.85).aspx), last checked on 07/10/2015

Setting the caret by clicking on elements, accepting keyboard input and modifying text nodes is handled entirely by the browser. No further scripting is necessary.

The API enabled can be called globally on the `document` object, but will only execute when the user's selection or caret is focussed inside an element in editing mode. Table A.1 lists the full HTML editing API. To format text, the method `document.execCommand` can be used. Calling

```
1 document.execCommand('italic', false, null);
```

Listing 3.2: Emphasizing text using the HTML editing API

will wrap the currently selected text inside an element in editing mode with `<i>` tags. The method accepts three parameters. The first parameter is the "Command Identifier", that determines which command to execute. For instance, this can be `italic` to italicize the current selection or `createLink` to create a link with the currently selected text as label.

```
1 document.execCommand('createLink', false, 'http://google.de/');
```

Listing 3.3: Creating a link using the HTML editing API

The *third* parameter will be passed on to the internal command given as first parameter. In the case of a `createLink` command, the third parameter is the URL to be used for the link to create. The *second* parameter determines if executing a command should display a user interface specific to the command. For instance, using the `createLink` command with the second parameter set to `true` and not passing a third parameter, the user will be prompted with a system dialog to enter a URL. A full list of possible command identifiers can be found on MSDN⁸.

⁸[https://msdn.microsoft.com/en-us/library/ms533049\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/ms533049(v=vs.85).aspx), last checked on 07/10/2015

3.2.2 Development of HTML Editing APIs

With the release of Internet Explorer 5.5 and the introduction of editing capabilities, Microsoft released a short documentation⁹, containing the attributes' possible values and element restrictions along with two code examples. Although a clear purpose has not been stated, the code examples demonstrated how to implement rich-text input fields with it. Mark Pilgrim, author of the "Dive into" book series and contributor to the the Web Hypertext Application Technology Working Group (WHATWG), also states that the API's first use case has been for rich-text editing¹⁰.

In March 2003, the Mozilla Foundation introduced an implementation of Microsoft's designMode, named Midas, for their release of Mozilla 1.3. Mozilla already named this "rich-text editing support" on the Mozilla Developer Network (MDN)¹¹. In June 2008, Mozilla added support for contentEditable IDL and contenteditable content attributes with Firefox 3.

Mozilla's editing API mostly resembles the API implemented for Internet Explorer, however, to this present day, there are still differences (compare¹²¹³). This includes the available command identifiers¹⁴¹⁵ as well as the markup generated by invoking commands¹⁶.

In June 2006, Opera Software releases Opera 9¹⁷, providing full support for contentEditable and designMode¹⁸, followed by Apple in March 2008¹⁹ providing full

support Safari 3.1²⁰. MDN lists full support in Google Chrome since version 4²¹, released in January 2010²².

Starting in November 2004, WHATWG members have started actively discussing to incorporate these editing APIs in the HTML5 standard. Through reverse engineering, the WHATWG developed a specification based on Microsoft's implementation²³ and finally decided to include it in HTML5. With W3C's cooperation and the split in 2011, similar editing APIs based on this work are now included in W3C's HTML5 Standard²⁴ and WHATWG's HTML Standard²⁵.

3.2.3 Emergence of HTML editing JavaScript libraries

Around the year 2003²⁶ the first JavaScript libraries emerged that made use of Microsoft's and Mozilla's editing mode to offer rich-text editing in the browser. Usually these libraries were released as user interface components (text fields) with inherent rich-text functionality and were only partly customizable.

In May 2003 and March 2004 versions 1.0 of "FCKEditor"²⁷ and "TinyMCE" have been released as open source projects. These projects are still being maintained and remain among the most used rich-text editors. TinyMCE is the default editor for Wordpress and CKEditor is listed as the most popular rich-text editor for Drupal²⁸.

Since the introduction of Microsoft's HTML editing APIs, a large number of rich-text editors have been implemented. While many have been abandoned, GitHub lists about 600 JavaScript projects related to rich-text editing²⁹. However, it should be noted, that some projects only use other projects' editors and some projects are stubs.

Popular choices on GitHub include "MediumEditor", "wysihtml", "Summernote" and others.

3.2.4 Usage of HTML Editing APIs

Most rich-text editors use HTML editing APIs as their basis. CKEditor and TinyMCE dynamically create an `iframe` on instantiation and set its `body` to editing mode using `contenteditable`. Doing so, users can type inside the `iframe` so it effectively acts as text input field. Both libraries wrap the `iframe` in a user interface with buttons to format the `iframe`'s contents. When a user clicks on a button in the interface `document.execCommand` will be called on the `iframe`'s `document` and the selected text will be formatted. While using an `iframe` is still in practice, many newer editors use a `div` instead. The advantages and disadvantages of this technique will be discussed in Sections XY.

3.2.5 Standardization of HTML Editing APIs

It makes sense to use HTML editing APIs for rich-text editing. Microsoft's demos published with the release of these API suggest to do so. Mozilla picked up on it and called their implementation "rich-text editing API". Other browsers followed with APIs based on Microsoft's idea of editable elements. However, it would have been imaginable for browsers to offer a native user interface component, a dedicated rich-text input field.

The HTML editing APIs have only been standardized with HTML5, which itself introduces 13 new types of input fields³⁰, but none with rich-text capabilities. The WHATWG discussed various ways to specify rich-text editing for the upcoming HTML5 standard, including dedicated input fields. The issues that have been faced with that idea are

1. Finding a way to tell the browser which language the rich-text input should

³⁰<https://developer.mozilla.org/en/docs/Web/HTML/Element/Input>, last checked on 07/16/2015

generate. E.g. should it output (the then popular) "bb" code, (X)HTML, Textile or something else?

2. How can browser support for a rich-text input be achieved?

Ian Hickson, editor of WHATWG and author of the HTML5 specification addresses these main issues in a message from November 2004³¹. He states

Realistically, I just can't see something of this scoped[sic] [the ability to specify a input 'language' for a text-area and possibly to specify a subset of language elements allowed] getting implemented and shipped in the default install of browsers.

and agrees with Ryan Johnson, who states

Anyway, I think that it might be quite a jump for manufacturers. I also see that a standard language would need to be decided upon just to describe the structure of the programming languages. Is it worth the time to come up with suggestions and examples of a programming language definition markup, or is my head in the clouds?

Ian Hickson finally concludes

Having considered all the suggestions, the only thing I could really see as being realistic would be to do something similar to (and ideally compatible with) IE's "contentEditable" and "designMode" attributes.

Mark Pilgrim lists this as milestone of the decision to integrate Microsoft's HTML editing APIs in the HTML5 standard.³²

³¹<https://lists.w3.org/Archives/Public/public-whatwg-archive/2004Nov/0014.html>, last checked on 07/16/2015

³²<https://blog.whatwg.org/the-road-to-html-5-contenteditable>, last checked on 07/16/2015

3.2.6 HTML Editing APIs are questionable

Understanding the history of the HTML editing APIs, the reasons for their wide browser support and their final standardization are questionable. It can be doubted if they fit their purpose specifically well. In fact, all major browsers simply mimicked the API as implemented in Internet Explorer 5.5. The reasons for this have not been publically discussed. A reason may have been to be able to compete with the other browsers in terms of features. Both, Microsoft's original implementation as well as Mozilla's adoption have been released in the main years of the so-called "browser wars". However, applying practically no change to the API, it can be argued that compatibility, being able to display websites implemented for Internet Explorer, may have been a central factor for Mozilla. Other now popular browsers, i.e. Chrome, Safari and Opera, implemented these APIs only years later, when JavaScript libraries based on them have already been popular and widely used, which could have been an influence on these decisions. It has clearly been stated (see section 3.2.5), that the reason for standardizing these APIs have mostly been to ensure browser support.

The API itself stems from the time when the usage of the web was different from today, its future was still unknown and web applications like Google Docs have not even been thought of. It should be discussed if this API really is the answer to all problem and if it still fits (or ever fit) modern requirements for content management systems or web application. The advantages, disadvantages and practical issues will be discussed in sections x y z.

3.2.7 Advantages of HTML Editing APIs

HTML Editing APIs have some notable advantages which will be discussed in this section.

Browser support A fair reason for using HTML editing APIs is its wide browser support. caniuse.com lists browser support for 92.78% of all used web browsers³³.

³³<http://caniuse.com/search=contenteditable>, last checked on 07/17/2015

I.e. 92.78% of all people using the web use browsers that have full support for HTML editing APIs.

High-level API HTML editing APIs offer high-level commands for formatting text. It requires little setup to implement basic rich-text editing. The browser takes care of generating the required markup.

HTML output HTML editing APIs modify and generate HTML. In the context of web development, user input in this format is likely to be useful for further processing.

No need for language definitions The WHATWG discussed dedicated rich-text inputs, for instance as an extension of the `textarea` component. Offering a native input for general rich-text input brings up the question which use-cases this input conforms. For a forum software, it might be useful to generate "BB" code, while for other purposes other languages might be needed. Offering HTML editing APIs offers a semantically distinct solution, while still enabling a way to implement rich-text editing.

Possible third-party solutions for other languages While HTML editing APIs can be used to generate HTML only, third-party libraries can build on top of that by implementing editors that write "BB" code (for instance) and use HTML only for displaying it as rich-text.

3.2.8 Disadvantages of HTML Editing APIs

No specification on the generated output The specifications on the HTML editing APIs do not state what markup should be generated by specific commands. There are vast differences in the implementations of all major browsers. Calling the `italic` command, this is the output of Internet Explorer, Firefox and Chrome:

```
1 <i>Lorem ipsum</i>
```

Listing 3.4: Markup of italic command in Internet Explorer

```
1 <span style="font-style: italic;">Lorem ipsum</span>
```

Listing 3.5: Markup of italic command in Firefox

```
1 <em>Lorem ipsum</em>
```

Listing 3.6: Markup of italic command in Chrome

This is a *major* problem for web development, because it makes processing input very difficult. Given the number of possible edge cases, it is very hard to normalize the input. Apart from that Internet Explorer's output is semantically incorrect for most use cases³⁴ while Firefox's output is breaking semantics entirely and considered a bad style regarding the principle of the separation of concerns³⁵. The difference in the generated markup affects many commands but also the browser's native behaviour. When a user enters a line break, Firefox will insert a `
` tag, Chrome and Safari will insert a `<div>` tag and Internet Explorer will insert a `<p>` tag.

Flawed API The original and mostly unaltered API is limited and not very effective. MDN lists 44 commands available for their `execCommand` implementation³⁶. While other browsers do not match these commands exactly, their command lists are mostly similar. 17 of those commands format the text (for instance to italicize or make text bold) by wrapping the current selection with tags like `` or `strong`. The only difference between all commands is which tag will be used. At the same time there is no command to wrap the selected text in an arbitrary tag, for instance to apply a custom class to it (`Lorem ipsum`). All 17 commands could be summarized by a single command that allows to pass custom tags or markup and wraps the selected text with it. This would not only simplify the API, but would also give it enormously more possibilities. The same goes for insert-

³⁴<https://developer.mozilla.org/en-US/docs/Web/HTML/Element/i#Notes>, last checked on 07/17/2015

³⁵https://en.wikipedia.org/wiki/Separation_of_concerns#HTML.2C_CSS.2C_JavaScript, last checked on 07/17/2015

³⁶<https://developer.mozilla.org/en-US/docs/Web/API/document/execCommand#Commands>, last checked on 07/17/2015

ing elements. 7 commands insert different kinds of HTML elements, this could be simplified and extended by allowing to insert any kind of (valid) markup or elements with a single command.

Both alternatives would also give developers more control of what to insert. As previously described, browsers handle formatting differently. Allowing to format with specific HTML would generate consistent markup (in the scope of a website) and allow developers generate the markup fitting their needs.

Clipboard Pasting pasting is a problem: shitty markup can be pasted, paste event not implemented in all browser, some offer a modal, some clean up after change. I can solve this problem.

Bugs The HTML editing API is prone to numerous bugs across all browsers. Most editors do not really work. This renders an "easy and quick" implementation of this seemingly high-level (quick) API unusable.

it seems to me the api as provided is a bad idea. Programmers can handle control, and why not make this control specific instead of executing bulkish commands. very limited api. limited wo a few commands and a few paramters No specifications on what markup to generate (mozilla != ie, mdn has links for that)

3.2.9 Evening out varying browser behaviour

huge editor libraries, developed for 10 years trying to fix stuff libraries, not editors targeting inconsistencies they all can never know what's gonna happen

3.2.10 DOM manipulation without Editing APIs

In October 1998 the World Wide Web Consortium (W3C) published the "Document Object Model (DOM) Level 1 Specification". This specification includes an API on how to alter DOM nodes and the document's tree³⁷. It provided a standardized way

³⁷<http://www.w3.org/TR/REC-DOM-Level-1/level-one-core.html>, last checked on 07/10/2015

for changing a website's contents. With the implementations of Netscape's JavaScript and Microsoft's JScript this API has been made accessible to web developers.

3.2.11 Advantages of rich-text editing without Editing APIs

Only this can guarantee the same behaviour and the same output across all browsers. It puts the contenteditable implementation in the hand of JavaScript developers. We no longer have to wait for browsers to fix issues *and conform each other* and thus can be faster, at least possibly, than browsers are. Also we can deploy updates immediately to all users and do not have to worry they use old browsers even if updates exist.

The API is flawed but as Ian something of whatwg pointed out, it's hard to ensure browser support so changing the API is difficult (but not impossible). Rolling out a JS lib using non-editing APIs would work instantly, everywhere.

3.2.12 Disadvantages of rich-text editing without Editing APIs

Apparently implementing editing is prone to a lot of bugs issues **and edge-cases**. It can be assumed that it is difficult to do so. / Discuss the issues discussed by WHATWG here. It's difficult to do this.

Also this can be seen as "yet another" implementation of contenteditable, equal to browser implementations. Just one more editor for developers to take care of. However, this isn't quite correct, cos developers usually can choose a single editor that is used for the entire project, so they only have to take care of a single editor.

3.2.13 Disadvantages of offering user interface components

Warum es besser ist eine library zu shippen und nicht einen editor als ui component iFrame hat vor und nachteile. mit meiner library kann es jeder so machen, wie er/sie es will

Chapter 4

Implementation

4.1 Conformity with HTML Editing APIs

Wie sehr passt meine library zu dein HTML Editing APIs Was definieren die? Was muss ich conformen, welche Freiheiten habe ich? <https://dvcs.w3.org/hg/editing/raw-file/tip/editing.html>

4.2 JavaScript library development

No IDEs, tools, not even conventions.

Not for building: Big JS libraries all do it differently. Top 3 client side JavaScript repositories (stars) on github <https://github.com/search?l=JavaScript&q=stars%3A%3E1&s=stars&ty>
Angular.js: Grunt d3 Makefile, also ein custom build script welche node packages aufruft jQuery custom scripts, mit grunt und regex und so

Not for Architecture Angular custom module system with own conventions d3 mit nested objects (assoc arrays) und funktionen jQuery mit .fn ACE mit Klassen, daraus habe ich gelernt

4.3 Ich habe verwendet

Gulp requireJs AMDClean Uglify

JSLint - Douglas Crockford coding dogmatas / conventions JSCS - JavaScript style guide checker

Livereload PhantomJs Mocha Chai

Durch Require und AMDClean schöne Arbeitsweise (am Ende über Bord geworfen) und kleine Dateigröße, wenig overhead.

Automatisierte Client side Tests mit PhantomJs und Mocha/Chai

4.4 Coding conventions

Habe mich größtenteils an Crockfordstyle orientiert, aber die Klassen anders geschrieben. Habe den Stil von ACE editor verwendet, denn der ist gut lesbar. Lesbarkeit war mir wichtiger als Crockford style. Für private Eigenschaften und Methoden habe ich die prefix convention verwendet. https://developer.mozilla.org/en-US/Add-ons/SDK/Guides/Contributor_s_Guide/Private_Properties Sie bewirkt keine echte accessibility restriction, aber es ist eine allgemein anerkannte convention und ist auch viel besser lesbar.

4.5 Coding Klassen

Ich habe mich für Klassen entschieden. Das hat folgende Vorteile:

- * Klassen sind ein bewährtes Konzept um Code zu kapseln, logisch zu strukturieren und lesbar zu verwalten
- * Durch prototypische Vererbung existiert die Funktionalität von Klassen nur 1x im Browser 7 RAM
- * Zudem gibt es Instanzvariablen, die für jede Type Instanz extra existieren und so mehrere Instanzen erlauben
- * Die Instanzvariablen sind meistens nur Pointer auf Instanzen anderer Klassen
- * Das ganze ist dadurch sehr schlank

4.6 Programmstruktur

Es gibt ein Basisobjekt, das ist die Type "Klasse". Darin werden dann die anderen Klassen geschrieben "Type.Caret", "Type.Selection", "Type.Range", ... Das hat den Vorteil dass das ganze ge-name-spaced ist, so dass ich keine Konflikte mit Systemnamen habe (Range) (und auch nicht mit anderen Bibliotheken) Effektiv gibt es eine (flache) Baumstruktur und so mit Ordnung. Für bestimmte Klassen, "Type.Event.Input", "Type.Input.Filter.X" geht es tiefer. Der zweite Grund ist, dass ich somit alle Klassen die ich geschrieben habe für Entwickler sichtbar bereit stelle und nicht implizit und versteckt für irgend nen Quatsch.

Ursprünglich ein MVC konzept geplant mit einem Document Model und verschiedenen Renderern, aber für den haufen geworfen.

Ich werde jetzt die einzelnen Module erklären

4.7 Type

Die Type

4.8 Caret

caret

4.9 Range

range

4.10 Selection

selection

4.11 Selection Overlay

overlay

4.12 Input

input

4.13 Formatting

formatting

4.14 Change Listener

change

4.15 Contents

contents

4.16 Development

developmment

4.17 Dom Utilities

dom util

4.18 Dom Walker

dom walker

4.19 Environment

env

4.20 Core Api

core api

4.21 Event Api

ev api

4.22 Events

Input input event only event required so far

4.23 Input Pipeline

pipeline ideas

Caret caret

Command command

Headlines head lines

Line Breaks line breaks

Lists lists

Remove remove

Spaces spaces

4.24 Plugin Api

plugin api

4.25 Settings

settings

4.26 Text Walker

text walker

4.27 Utilities

util

Appendix A

Tables

Method	Description
execCommand	Executes a command.
queryCommandEnabled	Returns whether or not a given command can currently be executed.
queryCommandIndeterm	Returns whether or not a given command is in the indeterminate state.
queryCommandState	Returns the current state of a given command.
queryCommandSupported	Returns whether or not a given command is supported by the current document's range.
queryCommandValue	Returns the value for the given command.

Table A.1: HTML Editing API
